## MONOTONE MAPPINGS BETWEEN SOME KINDS OF ORDERED SETS

Đuro Kurepa, Zagreb

Dedicated to Professor A. D. Wallace  
for his 60<sup>th</sup> birthday

### 0. Introduction.

$(O, <)$  or simply  $O$ , like  $(O_1, <_1)$ ,  $(O_2, <_2)$  will denote sets  $O, O_1, O_2$ , ordered (totally or partially) by means of  $<, <_1, <_2, \dots$  respectively.

**0.1.** If  $(O_1, <_1)$  and  $(O_2, <_2)$  are (partially or totally) ordered sets, a mapping  $f$  from  $O_1$  to  $O_2$  is said to be increasing (isotone, order preserving) or a member of

$$\uparrow = ((O_1, <_1), (O_2, <_2)) = \{f; x \in O_1 \implies f x_1 \in O_2\},$$

provided

$$\{x, y\} \subseteq O_1 \wedge x \leq_1 y \implies f x \leq_2 f y;$$

if moreover  $x <_1 y \implies f x <_2 f y$ ,  $f$  is said to be strongly or strictly increasing.

**0.2.** The set of all increasing functions from  $(O_1, <_1)$  to  $(O_2, <_2)$  is denoted by

$$\uparrow = ((O_1, <_1), (O_2, <_2)) \quad (1)$$

or shorter by  $\uparrow = (O_1, O_2)$ .

**0.3.** The set of all strongly increasing functions from  $(O_1, <_1)$  to  $(O_2, <_2)$  is denoted by

$$\uparrow((O_1, <_1), (O_2, <_2)) \text{ or } \uparrow(O_1, O_2). \quad (1)$$

An important problem is to determine the last set, for given  $O_1, O_2$ .

**0.4.** Varying the sets  $(O_1, <_1)$ ,  $(O_2, <_2)$ , one is varying considerably the sets **0.2(1)** and **0.3(1)**. In particular, the problem arises to determine the existence of some member of the set (1) having a certain given property. Among the ordered sets some are quite characteristic, like  $(PS, \sqsubset)$ ,  $\eta_a$ , lattices, etc.

Ovaj rad je financirao Savezni fond za naučni rad i Republički fond za naučni rad SRH.

**0.5.** Partitive sets  $PS, P'S, P_aS$  etc.

For any set  $S$  one defines  $PS = \{X; X \subseteq S\}$ ,  $P'S = \{X; O \subset \subset X \subseteq S\}$ ,  $P_aS = \{X; X \subseteq S \wedge kX < a\}$ ;  $a$  is a given cardinal number.

**0.6.** Left ideals of  $(O, <)$ . Operator  $IO$ .

$IO$  or  $I(O, <)$  consists of all the initial section or left ideals of  $(O, <)$ ; in other words

$$X \in I(O, <) \Leftrightarrow X \subseteq O \wedge (X = \emptyset \vee x \in X \rightarrow O(\cdot, x] \subseteq X),$$

where

$$O(\cdot, x] = \{y; y \in O \wedge y \leq x\}.$$

Then one has the graphs or diagrams  $(I(O, <), \subset)$  and  $(I(O, <), \supset)$ .

**0.7.** The set  $w(O, <)$  (resp.  $w'(O, <)$  or  $\omega(O, <)$ ) consists of all the well-ordered subsets of  $(O, <)$ , the empty set  $\emptyset$  being included (being not included).

**0.8.**  $w'_0 = \sigma(O, <) = \{x; x \in w(O, <) \wedge x \neq \emptyset, x \text{ is bounded in } (O, <)\}$ .

**0.9.**  $w_0(O, <) = \{x; x \text{ is a well-ordered bounded subset of } (O, <)\}$ .

**0.10.** The operators  $L, L_0, L', L'_0$ .

$L(O, <)$  consists of all the chains of  $(O, <)$ ,

$L'$  consists of all the non empty members of  $L(O, <)$ ,

$L_b$  consists of all the bounded members of  $L(O, <)$ ,

$L'_b$  consists of all the non empty bounded members of  $L(O, <)$ .

**0.11.** Operators  $-L, -L_b, -L', -L'_b$  (anti  $L$ , anti  $L'$ , etc.).

The definition is obtained from Section 0.10 by replacing chains by antichains.

**0.12.** Relations  $-|, |-$ . Relations  $=|, |=$ .

For sequences or ordered sets  $A, B$  the relation  $A -| B$  or  $B |- A$  means that  $A$  is a proper initial section of  $B$ ; we set

$$A =| B \Leftrightarrow A = B \wedge A -| B.$$

Thus, for a given  $(O, <)$ , we have the ordered sets  $(X(O, <), -|)$ , for the operators  $X \in \{w, w_0, w', w'_0, L, L_0, L', L'_0\}$ .

Instead of  $w'_0$ , we wrote previously  $\sigma$ . All these sets are trees.

**0.13.** Left ideal closure. Right ideal closure.

For  $X \subseteq (O, <)$ , let

$$0X = \bigcup_x O(\cdot, x], \quad (x \in X); \quad 0\emptyset = \emptyset,$$

$$1X = \bigcup_x O[x, \cdot), \quad (x \in X); \quad 1\emptyset = \emptyset.$$

Consequently,  $0X$  (resp.  $1X$ ) is the minimal initial (terminal) section of  $(O, <)$  containing the set  $X$ .

**0.14.** For any family  $F$  of sets  $\subseteq (O, <)$  we put

$$0F = \{0X; X \in F\},$$

$$1F = \{1X; X \in F\}.$$

In particular we have the diagrams

$$(0w(O, <), \subseteq), (0L(O, <), \subseteq), (0\sigma(O, <), \subseteq), (0A(O, <), \subseteq), \text{ etc.}$$

**0.15.** Stellarity number  $s(O, <) = \inf \{kF; F \text{ being composed of chains } \subseteq (O, <) \text{ and } \bigcup_{X \in F} X = O\}$ .

**0.16.** Antistellarity number  $-s(O, <) = a(O, <) = \inf \{kF; F \subseteq \subseteq A(O, <) \wedge \bigcup F = O\}$ .

**0.17.** Number  $\Gamma(O, <)$ .

The first ordinal number, which is not imbeddable in  $(O, <)$ , is denoted by  $\Gamma(O, <)$  or  $\Gamma O$ .

**0.18.** The consideration of the sets  $(wO, -|), \uparrow((wO, \rightarrow)(O, <))$  was initiated by the present author who proved in particular that  $\uparrow(\sigma X, X) = \emptyset$ , for  $R \in \{Ra, Re\}$ ; the topic was then studied by S. Ginsburg [1] (Theorem 10) who proved in particular that  $\uparrow i(O, \rightarrow), (O, <) = \emptyset$ , for every infinite totally ordered group  $(O, <)$  and for  $i = \omega$ ; if moreover  $(O, <)$  is a totally ordered field, then one could write also  $i = \sigma$ .

An ordered set  $(O, <)$  is called by Ginsburg a  $k$ -set or a  $k'$ -set according as to whether the set

$$\uparrow((wO, -|), (O, <)) \tag{1}$$

is empty or non-empty; every member of the set (1) is called by Ginsburg a  $k$ -function on  $O^1$ .

1. Some theorems on strictly increasing functions.

**1.1. Theorem.**  $\uparrow((w(O, <), -|), (O, <)) = \emptyset$ , for every ordered set (cf. **0.1, 0.5.2, 0.5.6**). There exists no strictly increasing mapping of the set  $(w(O, <), -|)$  into the set  $(O, <)$ ; in other words, for any non-empty ordered set  $(O, <)$  and increasing mapping  $f$  from  $(wO, -|)$  into  $(O, <)$  there exists a well-ordered subset  $W$  of  $(O, <)$

---

<sup>1</sup> »Question. Do there exist two  $k'$ -sets  $E$  and  $F$  such that  $E \times F$  is a  $k$ -set?« ([1], p. 588.) (if  $E, F$  are both simply ordered  $k$ -sets, so is also  $E \times F$ , this set being ordered by the method of the last differences ([1], p. 587, Theorem 8).

on which the function  $f$  is constant and  $kW > 1$ . Symbolically,  $\uparrow(wO, O) = \emptyset$ , for every  $(O, <)$ . (D. Kurepa [11], théorème 1)<sup>2</sup>.

Proof. Suppose, on the contrary, that there exists a mapping  $f: (wO, -|) \rightarrow (O, <)$  such that  $x -| x'$  in  $wO \Rightarrow fx < fx'$ .

Since the void set  $\emptyset$  is a member of  $wO$  satisfying  $\emptyset -| x$ , for every non empty set  $x \in wE$ , one should have

$$f\emptyset < fx \quad (x \in wE, x \neq \emptyset).$$

Let

$$x_1 = f\{fe_0\}; \text{ then } x_0 < x_1; \text{ if } x_2 = f\{fe_1\},$$

$$e_0 = \emptyset, e_1 = e_0 \cup \{fe_0\} = \{fe_0\}, e_2 = e_1 \cup \{fe_1\} = \{fe_0, fe_1\};$$

assume that  $0 < \alpha < \gamma E$  and that for every  $\alpha_0 < \alpha$  one has defined the well-ordered sets  $e_{\alpha_0}$  and that these sets form an  $\alpha$ -chain in the tree  $(wO, -|)$ , i. e. that  $\xi < \eta < \alpha_0 \Rightarrow e_\xi -| e_\eta$ ; let us define  $e_\alpha$  as  $e_{\alpha-1} \cup \{fe_{\alpha-1}\}$  or as the union of all the sets  $e_{\alpha_0}$ , where  $(\alpha_0 < \alpha)$ , according as to whether  $\alpha$  is of the first kind or of the second kind. The set  $e_\alpha$  should be a member of  $wE$ ; therefore  $fe_\alpha$  would be a member of  $(O, <)$ . Consequently, for every  $\alpha < \Gamma O$  (for  $\Gamma O$  see. 0.10) one would have the well-ordered set  $e_\alpha$  such that

$$\alpha < \beta < \gamma O \Rightarrow e_\alpha -| e_\beta;$$

therefore, by hypothesis,

$$\alpha < \beta < \gamma O \Rightarrow fe_\alpha < fe_\beta$$

and the elements

$$fe_\alpha \quad (\alpha < \gamma O)$$

would constitute a well-ordered subset of  $(O, <)$  of order type  $\gamma O$ , contradicting the definition of  $\Gamma O$  as the first ordinal not imbeddable into  $(O, <)$ .

$$\mathbf{1.2. Theorem.} \quad \uparrow((PO, \subset), (O, <)) = \emptyset, \quad (1)$$

$$\uparrow((PO, \supset), (O, <)) = \emptyset \quad (\text{cf. } \mathbf{0.1, 0.5}). \quad (2)$$

Proof. As a matter of fact, if  $f$  were a member of the set (1), then the restriction  $f_0$  of  $f$  in the set  $wO$  would yield (contrary to 1.1.) a member of  $\uparrow w((O, <), (O, <))$ , because for sets  $X, Y \in PO$ , the relation  $X -| Y$  implies  $X \subset Y$ .

<sup>2</sup> In Mathematical Reviews 17 (1956), 1065, reviewing this paper, S. Ginsburg writes: »Three results are stated, the first being incorrect [counterexample: Let  $E$  be the negative integers. For each subset  $S$  of  $E$  let  $f(S) = \max \{x | x \text{ in } E\} - 1$ «. This example is inadequate for the situation, because the void set which is a member of  $wE$  is omitted; this example shows that  $\uparrow((wE, -|), (E, <)) \neq \emptyset$ ; here  $(E, <)$  may stay for any inversely ordered set (S. Ginsburg [1], p. 586, Corollary).

The second part of the theorem is a consequence of the first part of the theorem and of the fact that every partitive set  $(PS, \sqsubset)$  is isomorphic to its dual  $(PS, \supset)$ .

**1.3. Theorem.** *If  $f \in \uparrow(iO, O)$  (where  $i = \omega$  or  $\sigma$ ), then  $f\{x\} > x$ , for no  $x \in O$ ; in particular, if  $(O, <)$  is a chain, then  $f\{x\} \leq x$ , for every  $x \in O$ .*

*Proof.* Suppose on the contrary that  $f$  be a strictly increasing mapping of  $(\omega O, -|)$  into  $(O, <)$  and that for some  $x_0 \in O$  one has  $x_0 < f\{x_0\}$ . Let  $x_1 = f\{x_0\}$  and  $f\{x_0, x_1\} = x_2, f\{x_0, x_1, x_2\} = x_3$ , etc. As in 1.1. one would define, for  $0 < \alpha < \Gamma(O, <)$ , the point  $x_\alpha = f\{x_0, x_1, \dots, x_{\alpha_0} \dots\}$   $\alpha_0 < \alpha$ , which yields the strictly increasing  $\gamma$ -sequence

$$x_0, x_1, \dots, x_\alpha, \dots \quad (\alpha < \gamma O),$$

contradicting the definition of  $\gamma O$ .

**1.4. Analogously, one proves the following**

**Theorem.** *If  $i \in \{\omega, \sigma\}$  and  $f \in \uparrow(iO, O)$ , then*

$$fY > X^3 \text{ for no } X \in iO.$$

The proof is analogous to the proof of Theorem 1.1. (replacing  $\phi$  by any  $X \in iO$  satisfying  $fX > X$ ).

**1.5. Theorem.** *If  $f \in \uparrow(\omega O)$  and if  $(O, <)$  is a left complete chain and the function  $f_0 x = f\{x\}$  is increasing in  $(O, <)$ , then the fixpoints of the function  $f_0$  constitute a non empty left complete ordered set.*

The theorem is a consequence of Theorem 1.3. and of the theorem 1 in Đ. Kurepa [12].

**1.6. Theorem.** *If  $\Gamma O > \omega$  (cf. 0.18), then  $\uparrow((P_{\aleph_0} O, \sqsubset), (O, <)) \neq \phi$ .*

*Proof.* It is sufficient to consider any infinite well-ordered subset  $\{c_0 < c_1 < \dots\}$  and, for any  $X \subseteq O$  satisfying

$$kX < \aleph_0, \text{ to put } fX = c_{kX}.$$

**1.7. Lemma.** *If  $kX < kO$ , for every  $X \in \omega O$ , then  $\uparrow((P_{kO} O, \sqsubset), (O, <)) = \phi$ .*

As a matter of fact, in this case  $\omega(O, \leq) \subseteq P_{kO} O$ ; consequently, if  $f$  were a strictly increasing mapping of  $(P_{kO} O, \sqsubset)$  into  $(O, <)$ , then the restriction of the same mapping on  $\omega(O, <)$  would yield a member of  $\uparrow(\omega(O, <), (O, <))$  contrary to Theorem 1.1.

**1.8. Theorem.**

$$\uparrow((P(O, <), \sqsubset), (O, <)) \cup \uparrow((P(O, <), \supset), (O, <)) = \phi. \quad (1)$$

<sup>3</sup> For ordered sets A, B one defines

$$A < B \iff \dot{A} \leq \dot{B}$$

$$A \leq B \iff \dot{A} \leq \dot{B}.$$

The first summand in (1) is empty because of Theorem 1.1. and of the inclusion  $w(O, <) \subseteq P(O, <)$ . The second summand in (1) is empty because the ordered sets  $(PO, \sqsubset)$ ,  $(PO, \supset)$  are isomorphic and moreover one has the following:

**1.8.1. Lemma.** *If  $i$  is an isomorphism from  $(O, <)$  onto  $(O_1, <_1)$ , then*

$$\uparrow((O, <), (O_2, <_2)) \neq \emptyset \Leftrightarrow \uparrow((O, <), (O_2, <_2)) \neq \emptyset.$$

*In particular,  $f \in \uparrow((O, <), (O_2, <_2)) \Rightarrow fi^{-1} \in \uparrow(O_1, O_2)$ .*

**1.9. Theorem.** *Let  $O$  be any subset of the set  $R$  of real numbers such that  $\Gamma O = \omega_1$  and let  $O$  be conditionally complete (i. e. contains  $\sup X$  of every bounded subset  $X$  of  $O$ ); then  $\uparrow(\sigma O, O) = \emptyset$ . In particular,  $\uparrow((\sigma R, -|), (R, <)) = \emptyset$ .*

The proof is based on the fact that the tree  $(\sigma Ra, -|)$  is not a union of  $\leq \aleph_0$  of its antichains (cf. Kurepa [10<sup>a</sup>] [9] p. 37, Theorem 2.1) the last proposition is implied by the equality  $\uparrow(\sigma Ra, Ra) = \emptyset$ ; the last formula was proved in Kurepa [10] p. 89, Theorem 3.1. and [10<sup>a</sup>] p. 40, Theorem 3.1; another proof was given by S. Ginsburg ([1], p. 588).

**1.9.1.** Now, let us suppose that there exists a strictly increasing mapping  $f$  of  $\sigma O$  into  $O$

$$f \in \uparrow(\sigma O, O). \quad (1)$$

**1.9.2.** For any  $X \in \sigma O$ , let  $\bar{X}$  be the closure of the set  $X$  in the ordered space  $(O, <)$ . Then  $x \in \sigma O \Rightarrow \bar{x} \in \sigma O$  and  $\{x, y\} \subset \sigma O$  and  $X -| Y$  yield  $\bar{X} = | \bar{Y}$ , the equality  $\bar{x} = \bar{y}$  holding if and only if the point  $\sup X$  is the last point in the well-ordered set  $Y$ ; then,  $\gamma X$  is of the second kind.

Firstly, since  $X$  is a non empty well-ordered bounded set, so is also  $\bar{X}$ ; therefore,  $\bar{x} \in \sigma O$ , the set  $O$  being, by assumption, conditionally right complete. Furthermore, if  $x -| y$ , then  $\sup x \in \bar{x} \subseteq \bar{y}$ ; if  $x \cup \{\sup x\} = y$ , then  $\bar{x} = \overline{x \cup \{\sup x\}} = \bar{y}$ , i. e.  $\bar{x} = \bar{y}$ .

Conversely,  $\bar{x} = \bar{y}$  and  $x -| y$  imply that the set  $y$  contains no point  $> \sup x$ ; and since  $y \setminus x \neq \emptyset$  (because of  $x -| y$ ), one has necessarily  $\sup x \in y$  and  $\sup x$  is the last point in  $y$ .

**1.9.3. Function  $g$ .**

For  $x \in \sigma O$ , let

$$g(x) = fx, \text{ provided } \Gamma x \text{ is of the first kind, and let}$$

$$g(x) = f\bar{x} \setminus \{\sup x\}, \text{ provided } \Gamma x \text{ is of the second kind}$$

(cf. 0.17; for well-ordered sets  $W$  the number  $\Gamma W$  coincides with the order type of  $W$ ).

One should have  $g \in \uparrow(\sigma O, O)$ , i. e.  $x, y \in \sigma O \wedge x -| y \Rightarrow \Rightarrow fx < fy$  and  $\{fx, fy\} \subset O$ .

Case  $\bar{x} - | \bar{y}$ . If  $\Gamma x, \Gamma y \in I$ , then  $g(x) = f(\bar{x}) < f(\bar{y}) = g(y)$ . If  $\Gamma x$  is of the first kind and  $\Gamma y$  of the second kind, then

$$g x = f \bar{x} < f(\bar{y} \setminus \{\sup y\}) = g y;$$

here occurs the sign because  $\bar{x} - | \bar{y} \setminus \{\sup y\}$  (a consequence of the relations  $x - | y, -\Gamma x + \Gamma y \geq \omega_0$ ). The remaining two cases:  $\Gamma x \in II \wedge \Gamma y \in I, \Gamma x \in II \wedge \Gamma y \in II$  are discussed in an analogous way.

Case  $\bar{x} = \bar{y}$ . Since  $x - | y$ , one has  $y = x \cup \{\sup x\}, \Gamma x \in II$ ; hence,  $g x = f(\bar{x} \setminus \{\sup x\}) = f(\bar{y} \setminus \{\sup x\}) < f(\bar{y}) = g(y)$ .

Consequently,  $f x < g y$ .

**1.9.4.** If  $x \in \sigma O$  and  $\Gamma x$  is of the second kind, then every immediate successor  $x^+$  of  $x$  is of the form  $x \cup \{b\}$  with  $b \in \sigma O [\sup x, \cdot)$  and  $g(x^+) \geq g(x \cup \{\sup x\}) > g(x)$ .

Firstly,  $x^+ = x \cup \{b\}$ ; secondly,

$$g x^+ = g(x \cup \{b\}) = f \overline{x \cup \{b\}} = f(\bar{x} \cup \{b\}) > f \bar{x} = g x.$$

**1.9.5.** Now let us conclude and show that there would be a strictly increasing function from  $\sigma R a$  to  $R a$ , contrarily to Theorem 3.1 in Đ. Kurepa [10].

For  $x \in R_0 \sigma O = \{y; y \in \sigma O \text{ with } \sigma O(\cdot, y) = \emptyset\}$ , let  $r_0(x)$  be such that  $r_0(x) \in R a$  and  $r_0(x) < g(x)$ . For every  $y \in \sigma O$  with  $\Gamma y \in I$  denote by  $y^-$  the immediate predecessor of  $y$ ; i. e. for every such  $y$  the point  $y^-$  is the last one in the set  $\sigma O(\cdot, y)$ ; let  $0 < a < \omega_1$  and suppose that on the set  $\sigma O(\cdot, a) = \cup R_\xi \sigma O (\xi < a)$  a strictly increasing function  $r_a$  be defined such that it takes values in the set  $(O, <)$  and that

$$r_\xi | \sigma O(\cdot, \xi) \quad (\xi < a) \tag{1}$$

be an  $a$ -sequence of the more and more extending functions; let us define also functions  $r_a(\sigma O(\cdot, a])$ , extending the functions (1), by setting, for every  $x \in R_a(\sigma O)$ , any member of  $(O, <)$  such that

$$\begin{aligned} r_{a-1}(x^-) < r_a(x) < g(x), \text{ provided } a \in (I), \\ g(x) < \uparrow r_a(x) < g(x \cup \{\sup x\}), \text{ provided } a \in II. \end{aligned}$$

The definition should be possible for every  $a < \omega_1 (= \gamma O)$ ; putting then  $r(x) = r_a(x)$ , for every  $x \in R_a \sigma O$  and every  $a < \gamma \sigma O$ , one should have  $r \in \uparrow (\sigma(O, <) - |), (R a, <))$ .

**1.9.6.** Let  $E = r \sigma O$ ; then the set  $\sigma O$  would be the union of the  $-|$ -antichains  $\neg r x (X \in O)$ ; since  $O \subseteq R a$ , this would mean that the set  $(\sigma O, -|)$  is a union of  $\leq \aleph_0$  antichains, thus, the anti-stellarity of  $(\sigma O, -|)$  would be  $\leq \aleph_0$ ,

$$\neg s(\sigma O, -|) \leq \aleph_0. \tag{1}$$

And this very relation is impossible, the implied relation (1) contradicting Theorem 1.10 which follows. This completes the proof of Theorem 1.9.

**1.10. Theorem.** *Let  $O$  be any subset of  $\bar{\eta}_0 (= \bar{R}a = Re)$  such that  $\Gamma O = \omega_1$ . Then the antistellarity number of the tree  $(\sigma O, -|)$  is  $\aleph_1$ ,*

$$-s(\sigma O, -|) = \aleph_1 \text{ (cf. 0.16, 0.12) .}$$

**Proof. 1.10.1.** At first, the ordered set of rationals is imbeddable into  $(O, <)$  i. e.

$$\text{order type } \eta \leq \text{order type } (O, <) . \quad (1)$$

We have two cases:

**1.10.1.1. First case:**  $kO = \aleph_0$ . Then (1) was proved in D. Kurepa [8] (p. 146, Theorem 1).

**1.10.1.2. Second case:**  $kO > \aleph_0$ . In this case

$$-s \sigma O = \aleph_1 \text{ (cf. Theorem 1.10) .}$$

As a matter of fact, the set  $Ra$  (or its type  $\eta$ ) is similar to a subset of  $(O, <)$ , i. e.  $\eta$  is imbeddable into  $O$ . In other words, let  $O_0$  be the set of all the points  $x_0$  of  $(O, <)$  which are not points of bilateral accumulation of  $(O, <)$ ; the set  $O_0$  is countable because every  $x_0$  is an extremal point of an interval  $I(x_0)$  of the set  $\bar{\eta} (= Re)$  and such that  $I(x_0) \cap O = \{x_0\}$ ; consequently, the sets  $\text{Int } I(x_0)$  ( $x_0 \in O_0$ ) are pairwise disjoint; therefore,  $kO_0 \leq \aleph_0$ ; this and  $kO > \aleph_0$  imply that the set  $O_1 = O \setminus O_0$  is of a cardinality  $\geq \aleph_1$  and has no consecutive points. According to a well-known theorem of Cantor, this implies that  $\eta_0$  is imbeddable in  $O_1$  and a fortiori in  $O$ . Thus, formula (1) is completely proved.

**1.10.2.** Any isomorphic imbedding of  $\eta_0$  into  $O$  implies an isomorphic imbedding of the tree  $(\sigma \eta, -|)$  into the tree  $(\sigma O, -|)$ ; therefore, one has

$$\text{order type } (\sigma \eta, -|) \leq \text{order type } (\sigma O, -|)$$

and hence, for the antistellarity numbers one has.

$$\mathbf{1.10.3. Lemma.} \quad -s(\sigma \eta, -|) \leq -s(\sigma O, -|) .$$

**1.10.4.** Now, in D. Kurepa [10], p. 87, Theorem 2.1 and [11] p. 37, Theorem 2.1 it was proved that  $-s(\sigma \eta, -|) = \aleph_1$ . This formula and Lemma 1.10.3. yield.

$$\mathbf{Lemma.} \quad -s(\sigma O, -|) \geq \aleph_1 .$$

**1.10.5.** The antistellarity number of the tree  $(\sigma O, -|)$  is  $\leq \aleph_1$ . For abbreviation, put  $T = (\sigma O, -|)$ . Then, denoting by  $R_0 X$  the set of all the initial elements of  $X$ , one has the following disjoint

partition of  $T$  into antichains  $R_\xi T$ :

$$T = R_0 T \cup R_1 T \cup \dots = \bigcup_{\xi} R_\xi T,$$

where  $R_\alpha T = R_0(T \setminus \bigcup_{\xi < \alpha} R_\xi T)$ , for every ordinal  $O < \alpha$ .

Now, certainly  $R_{\omega_1} = \emptyset$ ; otherwise, if  $a \in R_{\omega_1} T$ , then the union of the well-ordered subsets  $X \in T(\cdot, a)$  would yield a non-countable well-ordered set  $\subset \bar{\eta}$ , contradicting a well-known theorem of Cantor.

The two Lemmas 1.10.4, 1.10.5 yield the requested Theorem 1.10.

1.11. On the existence of strictly increasing functions and everywhere dense subsets.

If there exists a strictly increasing function from  $(O, <)$  to  $(O_1, <_1)$  and if  $X_1$  is an everywhere dense subset of  $(O_1, <_1)$ , does there exist also a strictly increasing function from  $(O, <)$  to  $(X_1, <_1)$ ? Not, necessarily!

Theorem. *There exist ordered sets  $(O, <)$ ,  $(O_1, <_1)$  such that  $\uparrow((O, <), (O_1, <_1)) \neq \emptyset$  and that for some everywhere dense part  $X_1$  of  $(O_1, <_1)$  one has  $\uparrow((O, <), (X_1, <_1)) = \emptyset$ ; in particular,*

$$\uparrow((wRa, -|), Re) \neq \emptyset \text{ and } \uparrow((w(Ra, -|), (Ra, <)) = \emptyset. \quad (1)$$

The last equality being a special case of Theorem 1.1, let us prove (1); even a stronger result holds:

1.12.  $\uparrow((PRa, \subset), (Re, <)) \neq \emptyset$  (Sierpiński [13], p. 240).

In fact, let  $r_1, r_2, \dots$  be a normal well-ordering of the set  $Ra$ ; for  $x_k \in Ra$ , put  $fx_k = \sum r_n^{-2}$ ,  $n$  satisfying  $r_n < k$ ; put also  $f\emptyset = 0$ ; then  $f$  is a member of the set in 1.12.

2. Intervention of the antistellarity number  $-sO$  (cf. 0.16).

The question of the existence of a strictly increasing mapping on any  $(O, <)$  into  $\eta_0$  or in general into  $\eta_\sigma$  is the subject of the following theorem.

2.1. Theorem. For any regular number  $\aleph_\sigma$  one has

$$-s(O, <) \leq \aleph_\sigma \Rightarrow \uparrow((S, <); \eta_\sigma);$$

in other words, if an ordered set  $(O, <)$  is the union of  $\leq \aleph_\sigma$  antichains, then there exists a strictly increasing mapping of  $(O, <)$  to  $(\eta_\sigma, <)$  (the case  $\sigma = 0$  was proved in D. Kurepa [7], p. 337, Theorem 1).

2.2. Proof.

2.2.1. Let

$$A_\xi (\xi < \alpha \leq \omega_\sigma) \quad (1)$$

be a sequence of pairwise disjoint antichains exhausting the set  $(O, \langle)$ . The case  $\alpha < \omega_\sigma$  offering no difficulty, let us consider that in (1) we have  $\alpha = \omega_\sigma$ . Set, for every  $0 < \nu < \omega_\sigma$ ,

$$F_\nu = \bigcup A_{\nu'}, (\nu' < \nu); \tag{2}$$

we shall define a sequence of one-valued functions  $f_\nu$  on  $F_\nu$  ( $\nu < \alpha$ ) such that  $f_\nu$  be an extension of  $f_{\nu'}$ , for every  $\nu' < \nu$ .

**2.2.2.** Let  $W_{\eta_\sigma}$  be any normal well-ordering of  $\eta_\sigma$ ; consequently, the order type  $\gamma W_{\eta_\sigma}$  is an initial ordinal  $\geq \omega_\sigma$ . To start with, let  $f_1 F_1 = R_0 W_{\eta_\sigma}$  (the set formed by the first member of  $W_{\eta_\sigma}$ ). Let  $1 < \nu < \alpha$  and suppose that, for  $1 < \nu' < \omega_\sigma$  and every  $\nu' < \nu$ , the following condition  $K(\nu')$  holds:

**2.2.3.** Condition  $K(\nu') : \Gamma f F_{\nu'}, \Gamma f F_{\nu'}^* < \omega_\sigma$ , where  $\Gamma(X, \langle)$  is the first ordinal which is not imbeddable into  $(X, \langle)$ . Let us define  $f_\nu$  on  $F_\nu$ . If  $\nu$  is of the second kind, we put, for every  $a \in F_\nu$ ,  $f_\nu(a) = f_{\nu'}(a)$ , where  $\nu' < \nu$  such that  $f_{\nu'}(a)$  be defined. The number  $\omega_\sigma$  being regular, one is aware that the condition  $K(\nu)$  holds.

**2.2.4.** If the number  $\nu$  is of the first kind, the function  $f_\nu$  shall extend the function  $f_{\nu-1}$  and coincide in  $F_{\nu-1}$  with  $f_{\nu-1}$ ; for  $a \in F_\nu \setminus F_{\nu-1}$ , let us consider the sets

$$f_{\nu-1} F_{\nu-1}(\cdot, a), f_{\nu-1} F_{\nu-1}(a, \cdot) F_{\nu-1}. \tag{1}$$

The condition  $K(\nu-1)$  implies that the first set in (1) is empty or cofinal to an ordinal number  $< \omega_\sigma$ , and that the second set in (2) is empty or coinital to the inverse of an ordinal number  $< \omega_\sigma$ ; by the property of  $\eta_\sigma$  one concludes that there exists some member of  $\eta_\sigma$  located between the two sets (1); the first such point occurring in the well-order  $W_{\eta_\sigma}$  shall be denoted by  $f_\nu(a)$ . This means that the function  $f_\nu | F_\nu$  is defined.

**2.2.5.** Let us prove that the condition  $K(\nu)$  holds. But this is implied by the fact that every non-empty open interval of the ordered set  $f_\nu F_\nu$  contains a point of  $f_{\nu-1} F_{\nu-1}$ , this resulting from the definition of  $f_\nu(a)$  as the first element in the well-ordering  $W_{\eta_\sigma}$  located between the two sets (1).

**2.2.6.** By transfinite induction,  $f_\nu | F_\nu$  is defined for every  $\nu < \omega_1$ ; putting

$$f = \sup f_\nu | F_\nu \quad (\nu < \omega_\sigma), \tag{1}$$

one obtains a requested member of the set  $\uparrow(O; \eta_\sigma)$ . Of course, the formula (1) means that  $\text{Dom } f = \bigcup \text{Dom } f_\nu$  ( $\nu < \omega_\sigma$ ) and that, for every  $x \in \text{Dom } f$ , one has  $fx = f_\nu x$ , for every  $\nu$  satisfying  $x \in \text{Dom } f$ .

**2.2.7.** Now, we have the relation

$$k \eta_\sigma = \aleph_\sigma \langle \rangle 2^{\aleph_\sigma - 1} = \aleph_\sigma,$$

for  $\sigma$  of the first kind, and

$$2^{\aleph_\xi} \leq \aleph_\sigma (\xi < \sigma),$$

for  $\sigma$  of the second kind (cf. F. Hausdorff [2], p. 180).

Consequently, one has the following.

**2.3.8. Theorem.**

$$[-s(O, <) \leq \aleph_\sigma \Leftrightarrow \uparrow((O, <), \eta_\sigma) \neq \emptyset] \Leftrightarrow \xi < \sigma \Leftrightarrow 2^{\aleph_\xi} \leq \aleph_\sigma,$$

for every regular  $\aleph_\sigma$ .

**2.4.** The converse of Theorem 2.1. One might wonder whether the converse of Theorem 2.1 holds. It is so, provided  $k \eta_\sigma = \aleph_\sigma$ . As a matter of fact, if  $f$  is a strictly increasing function of  $(O, <)$  to  $\eta_\sigma$ , one has

$$O = \bigcup_x f^{-1} x \quad (x \in \eta_\sigma).$$

Everyone of these summands being an antichain, the formula yields that the antistellarity of  $(O, <)$  is  $\leq \aleph_\sigma$  (it is to be noted that for every chain  $L$  one has  $\uparrow(O, L) \neq \emptyset \Rightarrow sO \leq kL$ ).

## MONOTONA PRESLIKAVANJA MEĐU NEKIM VRSTAMA UREĐENIH SKUPOVA

Đuro Kurepa, Zagreb

### Sadržaj

**0.2.** Skup svih uzlaznih (odnosno strogo uzlaznih) preslikavanja uređena skupa  $(O_1, <_1)$  u uređen skup  $(O_2, <_2)$  označuje se sa (1).

**0.3.** Analogno vrijedi i za strogo uzlazna preslikavanja.

**0.6.**  $IO$  označuje skup svih početnih komada uređena skupa  $(O, <)$ .

**0.7.**  $wO$  (odnosno  $w'O$  ili  $\omega O$ ) označuje skup svih dobro uređenih podskupova od  $(O, <)$  pri čemu prazni skup uključujemo (isključujemo).  $w_0O$  (odnosno  $w'_0O$ ) dobije se promatrajući samo omeđene članove.

**0.13.** Definicija od  $0X, 1X$  je dana odgovarajućim formulama u **0.13.**

**0.14.** Definicija od  $0F, 1F$ , za svaku obitelj  $F$  skupova, razabire se iz formula u **0.14.**

**1.1. Teorem.** Ne postoji čisto uzlazno preslikavanje od  $(w(O, <), -|)$  u  $(O, <)$ .

**1.9. Teorem.** Neka je  $O$  proizvoljan skup realnih brojeva sa svojstvom  $\Gamma O = \omega_1$  i koji sadrži  $\sup X$ , za svako omeđeno  $X \subseteq O$ ; tada je  $\uparrow(\sigma O, O) = \emptyset$ .

**1.10. Teorem.** Ako je  $O$  podskup skupa  $R$  realnih brojeva sa svojstvom  $\Gamma O = \omega_1$  tada vrijedi (1).

**2.1. Teorem.** Svaki regularni broj  $\aleph_0$  zadovoljava (1); drugim riječima, ako je uređen skup  $(O, <)$  unija od  $\leq \aleph_0$  antilanaca, tada postoji čisto uzlazna funkcija od  $(O, <)$  ka  $(\eta_0, <)$ .

(Primljeno 1. II 1964.)
